## Working principle

A spring $\mathbf{M}$ keeps a disk $\mathbf{B}$ in zero flow rate position. When the fluid flows through the disk at a specific speed, a force is made on the disk $\mathbf{B}$, moving it to an equilibrium position.
The distance covered by $\mathbf{B}$ depends on:

- The force of the fluid flow $F$.
- The relationship between areas A \& B.
- The force in opposition of the spring $\mathbf{C}$.

The equilibrium between forces $\mathbf{F}$ and the one generated by $\mathbf{C}$ defines the position of the disk $\mathbf{B}$, equivalent to flow rate.
The disk B, which contains a magnet $\mathbf{M}$, acts over the switches and/or the local indicator.
